

Artificial intelligence, or AI, includes computer systems that learn patterns from examples.

During training, an AI model adjusts its settings to get better at a task.

A language model learns patterns in text and predicts what bits of text might come next.

When you type a prompt, or instruction, the model uses those patterns to create a response.

AI can help brainstorm, explain ideas, and organize information.

But AI can sound confident and still get facts wrong, even about bananas.

If its training examples are unfair or incomplete, AI can give biased answers too.

Check important answers with trusted sources, and keep private information out of your prompts.

AI is a tool, so people still need to make the important decisions.
